Acknowledgements

The research presented in this senior thesis would not been possible if not for the many people's guidance, encouragement, and help. Foremost, I would like to thank my research adviser Dr. Claudio Campagnari for his constant support and mentorship, both in research and my student life in the past almost 3 years. He lead me into the field of High Energy physics and had provided personal attention to my progress along the way. He is also the one who suggested the research topic to me as a step up from what I have been doing.

At the same time, I would also like to thank Dr. Ulascan Sarica, who is the primary correspondent in physics analysis for this research at UCSB. It would not be possible for me to undertake such a complex analysis if not for his dedication and careful teaching.

Additionally, I would like to acknowledge the help from Nick Amin, who guided me personally in the summer of 2017 when I first joined the group. Nick has also helped me tremendously in both physics and technical issues and have provided many useful tools for physics and computing. In the same regard, I would like to thank Bennett Marsh and Sicheng Wang for their help and guidance in the past years.

Abstract

Constraints on the Higgs boson decay width from off-shell production decay into
Z-boson pair

by

Jiahong (Jerry) | Ling 凌嘉鸿

The discovery of the Standard Model (SM) Higgs boson at the Large Hadron Collider (LHC) was a major achievement of the experimental particle physics community in the 21st century. Though a fair portion of the physics analysis focus has shifted to Supersymmetry (SUSY) physics, the direct search of SUSY models has yield null result so far. Meanwhile, the many properties of Higgs are still to be measured.

In this analysis, we present constraints on the decay width of Higgs boson, Γ_H , by using the on-shell and off-shell decay rates of Higgs to a pair of Z bosons and both Z's decay to a pair of electrons or muons. The result represent the expected constraints using the physics events and CMS experiment detector response simulated data via Monte Carlo methods (MC). The data and expected results correspond to run 2018 which has an integrated luminosity of 59.7 fb^{-1} at center-of-mass energy of 13 TeV.

Chapter 1

Introduction

In this chapter I present a brief introduction of the LHC physics and the physics behind the off-shell methods for constraining Higgs decay width.

1.1 Physics at LHC

- LHC
- CMS (trigger, PF, anti-Kt)

1.2 The physics of off-shell methods

Chapter 2

Methods

2.1 Event selection and physical variables

- Description of homebrew event variables and their physical significance
- DJJ_VBF prescription

2.2 Backgrounds

- Remarks on a few ‘fakeable’ physical objects
- a interference background in Higgs sample
- Base plots of variables, justify some cuts

2.3 Signal simulation reweighting

- Physics of Higgs signal sample (the weight, ME)
- the need for piecing together samples with different LHE Mass
- procedures
- plots
- results (also see appendix A)

2.4 Strategy in variable selection and binning

1

Chapter 3

Results and interpretation

Appendix A

Weights Table for Higgs Sample

Appendix B
